While an efficient load strategy can result in substantial savings and an improved environment, using synchronized SCR's will drastically increase the quality of the main supply. As described above, eliminating phase angle will remove harmful harmonics and RFI3 generation, which for example could disturb the IT infrastructure or overheat transformers. For customers already using full cycle firing, the PLM function achieves constant perfect power balance without the flicker effect.

Predictive Load Management (PLM) is able to eliminate those full cycle firing drawbacks resulting in more effective performance through load balancing and load shedding strategies. In most of the applications EPower makes it possible to switch from phase angle firing into full cycle firing mode.

One of the most common predictive models is the waterfall model. It assumes various phases in the SDLC that can occur sequentially, which implies that one phase leads into the next phase. In simple words, in waterfall model, all the phases take place one at a time and do not overlap one another.

Single-phase PWM rectifier has been widely applied in electric vehicle charger application. This paper proposes a model predictive control based on direct power control to improve the performance of single-phase converter, which is used to transfer electric energy between the grid and battery pack.
