The signal being processed is broken into simple components, each component is processed individually, and the results reunited. This approach has the tremendous power of breaking a single complicated problem into many easy ones. Superposition can only be used with linear systems, a term meaning that certain mathematical rules apply. Fortunately, most of the applications encountered in science and engineering fall into this category.

Linear Systems - Digital Signal Processing

The output response of a low-pass filter, which is a linear system, scales with the input signal. Now let's imagine that our system is a resistive heater. The input signal, $x(t)$, is a current produced by a current source, and the output signal, $y(t)$, is the heat generated by the resistive element.

Analog signal processing is for signals that have not been digitized, as in most 20th-century radio, telephone, radar, and television systems. This involves linear electronic circuits as well as nonlinear ones. The former are, for instance, passive filters, active filters, additive mixers, integrators, and delay lines.

In system analysis, among other fields of study, a linear time-invariant system is a system that produces an output signal from any input signal subject to the constraints of linearity and time-invariance; these terms are briefly defined below. These properties apply to many important physical systems, in which case the response y of the system to an arbitrary input x can be found directly using convolution: $y = x * h$ where h is called the system's impulse response and $*$ represents convolution.
